7/31/96 Martha
does this sound surprisingly?
-bake, geoff

undwater contours continue to indicate the direction of flow is almost due
th. This indicates well RRMW1 is in the correct position to monitor the
pact of the release. Table 3 shows all available groundwater measurements
wells near the site indicating well SMW1 was a foot higher in July of 1995
n on June 14th of 1996, thus indicating groundwater will probably rise at
st another foot, and maybe higher before the end of the irrigation season.
is flushing of water can be expected to further reduce the concentration of
in the groundwater based upon the rate of flow.

On June 13, a well at the Roadrunner (Well MW1) was pumped for 25
minutes at the rate of 15 gpm. The water level after 25 minutes was stable at a
drawdown of 0.71 feet. Thus, specific capacity is 21 gpm per foot of
drawdown. The Theis equation can be modified to calculate transmissivity
m specific capacity (Heath, 1983). Given a 12-inch effective diameter for
s well, and an estimate of the storage coefficient of 0.20 (see below), the
transmissivity for this well is estimated to be 2500 ft²/day. Because the
eened interval is 10 feet, hydraulic conductivity is on the order of 250
day. Water level measurements (June 14) show a hydraulic gradient of
125 ft/ft based on triangulation of three wells: RRMW1 at the Roadrunner
e, and Wapato Shell wells MW1 and MW3. The apparent direction of flow

good - But
is this under
static conditions?

where are
these wells in
relation to the
site?

Regionally, the unconfined aquifer beneath Wapato is known as the
ppenish alluvial aquifer, and has been described in detail by Bolke and
rivan (1981). In the Wapato vicinity, the saturated thickness of the aquifer
150 to 200 feet, and lateral hydraulic conductivity ranges from
proximately 270 to 430 ft/day. Storage coefficient (based on measurements
specific yield) is estimated at 0.20, and the direction of flow in the Wapato
cinity is generally SSE. Hydraulic gradient in the Wapato vicinity is shown
approximately 0.0024 ft/ft, based on March 1972 data. Water levels can vary
much as 15 ft seasonally within less than two miles of Wapato, primarily
cause of irrigation. The March 1972 data in the report reflect annual low
ater levels. Given the estimated 0.20 storage coefficient from Bolke and
rivan, we estimate the effective porosity is 0.25.

1972 data!

Given the hydraulic gradient observed in mid-June, an effective
porosity of 0.25, and using the hydraulic conductivity range of Bolke and
rivan, the rate of ground water flow is expected to be 14 to 22 ft/day at the
te.

Show
calculation
with reference
cited.

$$V = \frac{K}{n} \frac{dh}{dl}$$

270 → 430 ft/day
3 → 4.13 ft/day

$$V_1 = \frac{270}{.25} (.0024)$$

= 3 ft/day

$$V_2 = \frac{430}{.25} (.0024)$$

= 4.13 ft/day

The Washington State Department of Ecology, Yakama Indian Nation,
ity of Wapato, USCS and the School District have all been contacted to
etermine if there are any wells used for drinking water downgradient of the
elease. All residences in the City of Wapato are on City water. There are no
nown drinking water uses of this aquifer within the City of Wapato. The
nly uses of the aquifer are for irrigation of two City parks on Camas Avenue
